International Multidisciplinary Journal Metainnovate – IMJM

It is an official publication of YBN University, Rajaulatu Village, Namkum, Ranchi, Jharkhand -834010.India It is published quarterly - March, June, September, and December.

Vol.1(2026):Vol.1,Issue 2,April-June

Title: Evolution and Application of Artificial Intelligence

Dinesh Choudhary*
Sr Database Administrator, CPSE, Texas, USA

The development of artificial intelligence (AI) is closely linked to the four Industrial Revolutions that have influenced human history (Schwab, 2017). The initial Industrial Revolution, characterised by mechanisation and steam power from the late 18th to early 19th century, established the groundwork for mass production and urbanisation. The second Industrial Revolution, marked by electrification and assembly lines from the late 19th to early 20th century, advanced industrialisation significantly. The third Industrial Revolution, or Digital Revolution, commenced in

the mid-20th century with the introduction of computers, automation, and telecommunications, resulting in the digitalisation of society (Rifkin, 2011).

Computer technology and automation have been pivotal in every industrial revolution, facilitating efficiency, production, and innovation. The advent of computers has led to the automation of operations previously executed by humans, transforming industries including manufacturing, 1 transportation, and communication. This automation enabled the shift from manual labour to mechanised operations, transforming economies and societies globally (Brynjolfsson & McAfee, 2014).

The history of AI dates to the mid-20th century, when pioneers such as Alan Turing established the theoretical foundations for intelligent machines (Turing, 1950). Initial AI systems concentrated on rule-based logic and problem-solving, progressively advancing into intricate algorithms and neural networks (Russell & Norvig, 2021). Contemporary AI, propelled by progress in machine learning and deep learning, has accomplished significant achievements in domains such as natural language processing, computer vision, and robotics (LeCun, Bengio, & Hinton, 2015).

The use of AI across multiple areas offers significant advantages for society. In healthcare, AI applications encompass disease diagnosis, therapy, medication discovery, and personalised medicine. AI-powered diagnostic technologies evaluate medical images with remarkable precision, aiding healthcare practitioners in recognising anomalies and diagnosing diseases at initial stages (Topol, 2019). Furthermore, AI-driven predictive analytics evaluate patient data to foresee health concerns and customise preventive measures, thereby enhancing patient outcomes and decreasing healthcare expenses (Rajkomar et al., 2019).

Transportation constitutes another sector in which AI possesses significant potential. Autonomous vehicles, integrated with AI algorithms for perception, decision-making, and navigation, possess the capacity to transform transportation by improving safety, accessibility, and efficiency, while simultaneously decreasing traffic congestion and emissions (Goodall, 2014). AI-driven traffic management solutions enhance traffic flow in real-time, alleviating congestion and advancing urban mobility. Moreover, AI-driven predictive maintenance in transportation infrastructure proactively detects equipment malfunctions, reducing downtime and improving reliability (Lee, Kao, & Yang, 2014).

In finance, artificial intelligence algorithms are utilised for purposes including fraud detection, risk evaluation, and algorithmic trading. Fraud detection systems examine transactional data to discern

suspicious trends and abnormalities, allowing financial institutions to avert fraudulent operations and protect consumer assets (Bolton & Hand, 2002). Risk assessment models utilise machine learning approaches to assess creditworthiness, investment prospects, and market trends, thereby enabling informed decision-making and portfolio optimisation (Kraus & Feuerriegel, 2017). Algorithmic trading systems utilise AI algorithms to assess market data, execute trades, and refine trading strategies, facilitating swifter and more efficient transactions while reducing risks (Aldridge, 2013).

The influence of AI transcends conventional sectors, infiltrating domains such as scientific research, environmental conservation, and disaster management. AI-driven data analysis expedites discoveries across various fields, including genomics, medicine research, materials science, and astronomy (Jordan & Mitchell, 2015). Natural language processing methods enable knowledge acquisition and transdisciplinary cooperation. AI-driven monitoring systems in environmental conservation assess deforestation, oversee wildlife populations, and identify illicit activity, thereby enhancing conservation initiatives (Rolnick et al., 2019). AI-driven prediction models improve disaster planning and response by anticipating natural disasters, evaluating infrastructure weaknesses, and refining emergency response techniques (Reichstein et al., 2019).

Nonetheless, apprehensions regarding the societal ramifications of AI endure. Stephen Hawking cautioned against the possible hazards of unregulated AI advancement, including employment displacement, algorithmic prejudice, and autonomous weaponry (Cellan-Jones, 2014). Ethical questions pertaining to data privacy, surveillance, and the role of AI in intensifying inequality present substantial concerns (Zuboff, 2019). Addressing these concerns necessitates a comprehensive strategy that emphasises transparency, accountability, and inclusivity in the development and implementation of AI.

Responsible AI governance frameworks must tackle concerns including algorithmic bias, data privacy, and the ethical ramifications of AI applications. Collaboration across disciplines among policymakers, engineers, and stakeholders is crucial to guarantee that AI promotes the common good and maintains fundamental rights and values (Floridi et al., 2018). Furthermore, initiatives to enhance AI literacy and digital competencies are essential for enabling individuals and communities to comprehend and interact with AI technologies responsibly.

In conclusion, the prudent development and utilisation of AI are essential for maximising its promise while minimising its hazards. Harmonising innovation with ethical issues necessitates cooperation among policymakers, technologists, and the broader public. Promoting openness, accountability, and inclusion in AI development ensures that AI serves the common good and fosters a more equal and sustainable future for all.
